Administración del Mercado Eléctrico - URUGUAY.

México WindPower 4-5 de Marzo de 2020

República Oriental del URUGUAY

Area 176.215 km²
Population¹ 3.450.000 inhab
Pop. Density 19 inhab/km²
GPD² 59.6 USD Billions
GPD/inhab³ 14 600 USD/inhab
HDI⁴ 0.808 (position 57/189)

- ¹ Estimated 2018
- ² Gross National Product 2018
- ³ Year 2018
- ⁴ Human Development Index 2019

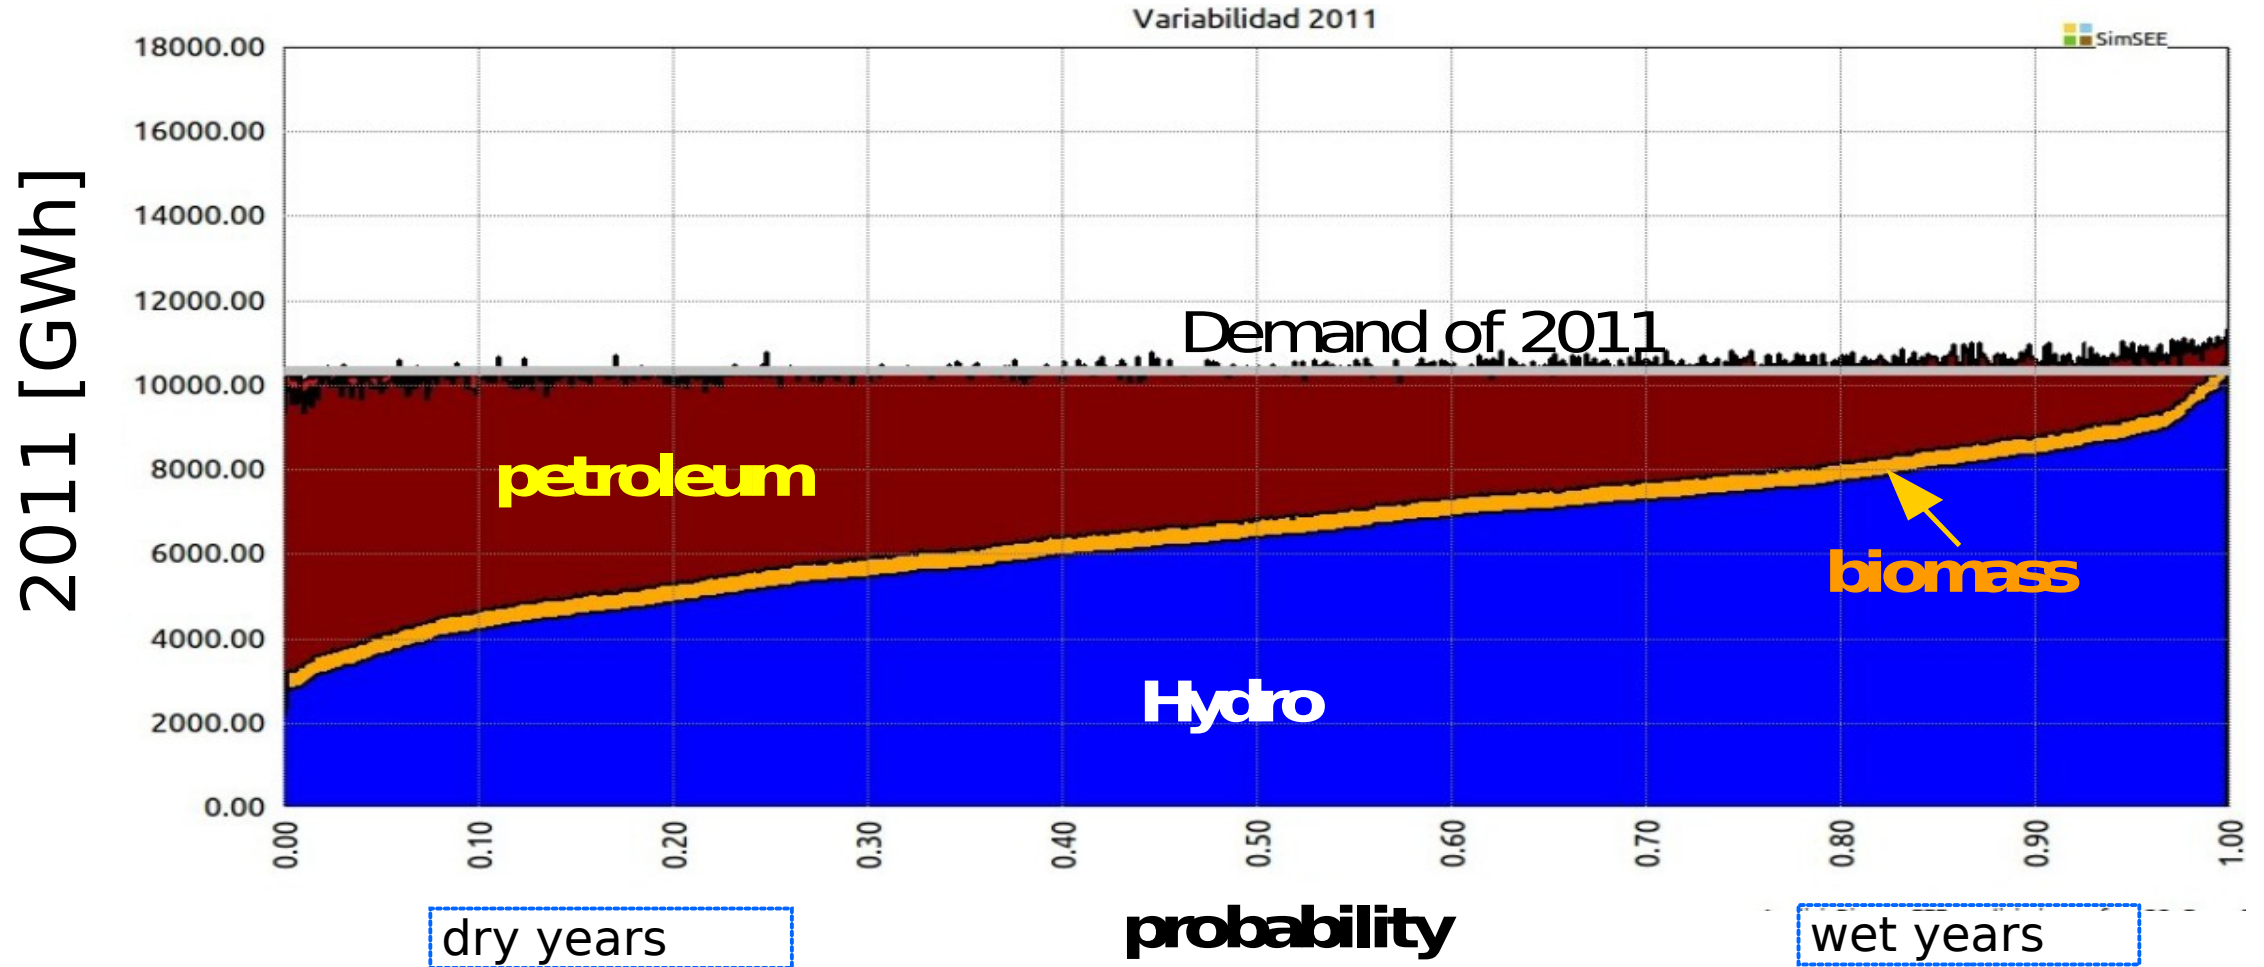

Each system has its peculiarities.

The optimal solution is surely different for each country.

In this presentation we will show how the Optimal Operation Programming of the National Integrated System in **Uruguay** is carried out with an installed wind and solar capacity that exceeds the peak of the system load in 70% of the days of the year

What we have done in Uruguay.

Source: The risk images are from the IIE studies carried out in 2010 and 2018 respectively.

What we have done in Uruguay.

Uruguay 2018.

Wind and Solar installed capacity compared with daily Demand.

Any 72 hours of January 2020 of the dispatch just as an example

Objective of the operation of the national interconnected system.

Provide energy with acceptable reliability and quality at the minimum cost.

- Centralized Dispatch.
- Only Variable Costs.
- Contracts are papers.

The System, The Operator and The Operation Policy

Operation Policy and The Cost of The Future

$$u = P(X, r, t)$$

$$CF_{PO}(X_{ahora}) = \left\langle \int_{ahora}^{+\infty} ce(X, r, u, t) dt \right\rangle$$

Temporary linking of decisions.

The use of stored resources (water) in the **present** produces an increase in **future** operating costs. The postponement of the use of a stored resource produces an increase in the costs of the present.

The **Optimal Policy** is the one that balances the cost impact between present and future.

Characterization of the variability in Uruguay.

water inflows

16 years

wind & solar

2 month

Time-Step used for simulation.

Big time step / implicit inertia

balance restrictions
overestimate filtering capacity

Small time step / more state variables

need of availability models to
represent
fail/repair inertia

Time-Bands (Patamares) defined by the Monotonous Load Curve ... Makes sense? Only an example, 4 days of July-2018-Uruguay

Source: ADME - SCADA ten-minute time series

Representation of uncertainty.

Sources of randomness Stochastic processes

- Demand and temperature
- Flows of water contributions
- Wind speed
- Solar radiation
- Price of interconnected markets
- Fuel prices
- Availability of fuels
- Availability of generating plants
- Availability of transport lines

El Niño, Hydro, Wind, Solar,
Demand, Temperature.
(correlated processes)

Equipment availability
(independent booleans)

We are managing faster dynamics, therefore, the correlation between the different resources has greater importance.

We need models of variability that correctly represent the correlation between resources and the correlation with the past.

That is, we have to represent the inertia behind the stochastic variables.

Availability of generators, power transmission lines, etc.

If we do not represent the state of the availability when simulating with small time-steps, the consequences of the inertia of the fault-repair process are underestimated.

Each generator, transmission line, etc. adds a Boolean state variable to the system.

CEGH modeling.

- reproduces the amplitude histograms of the original processes.
- reproduces the spatial and temporal correlations in a gaussian space.

*Gaussian World:
Multi-variable linear system
fed with*

Gaussian independent white noise

$$X_{k+1} = \sum_{h=0}^{h=n-1} A_h X_{k-h} + \sum_{h=0}^{h=m-1} B_h R_{k-h}$$

Accept state space reductions.
Accept forecast information.

NLT

NLT

NLT

NLT

NLT

NLT

*Real World
Model*

Bellman's curse of dimensionality.

CEGH

Ease of integration of FORECAST.

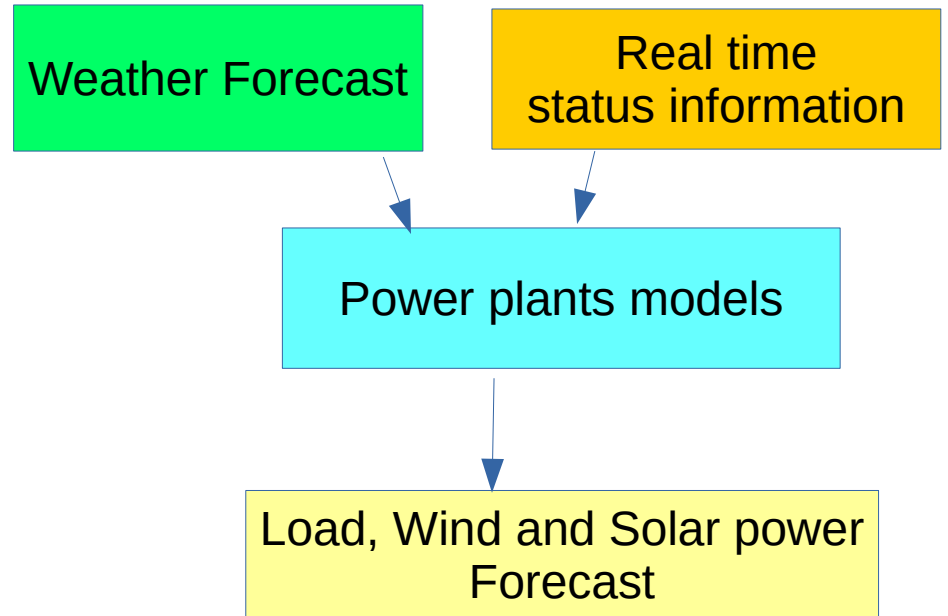

$$X_{k+1} = \sum_{h=0}^{h=n_r-1} A_h X_{k-h} + S_k + F_k \sum_{h=0}^{h=m-1} B_h R_{k-h}$$

The biases (S) change the 50% probability guide and the attenuation factors (F) regulate the noise injection, allowing to go from a Deterministic Forecast (null noise) to the disappearance of the forecast (historical noise).

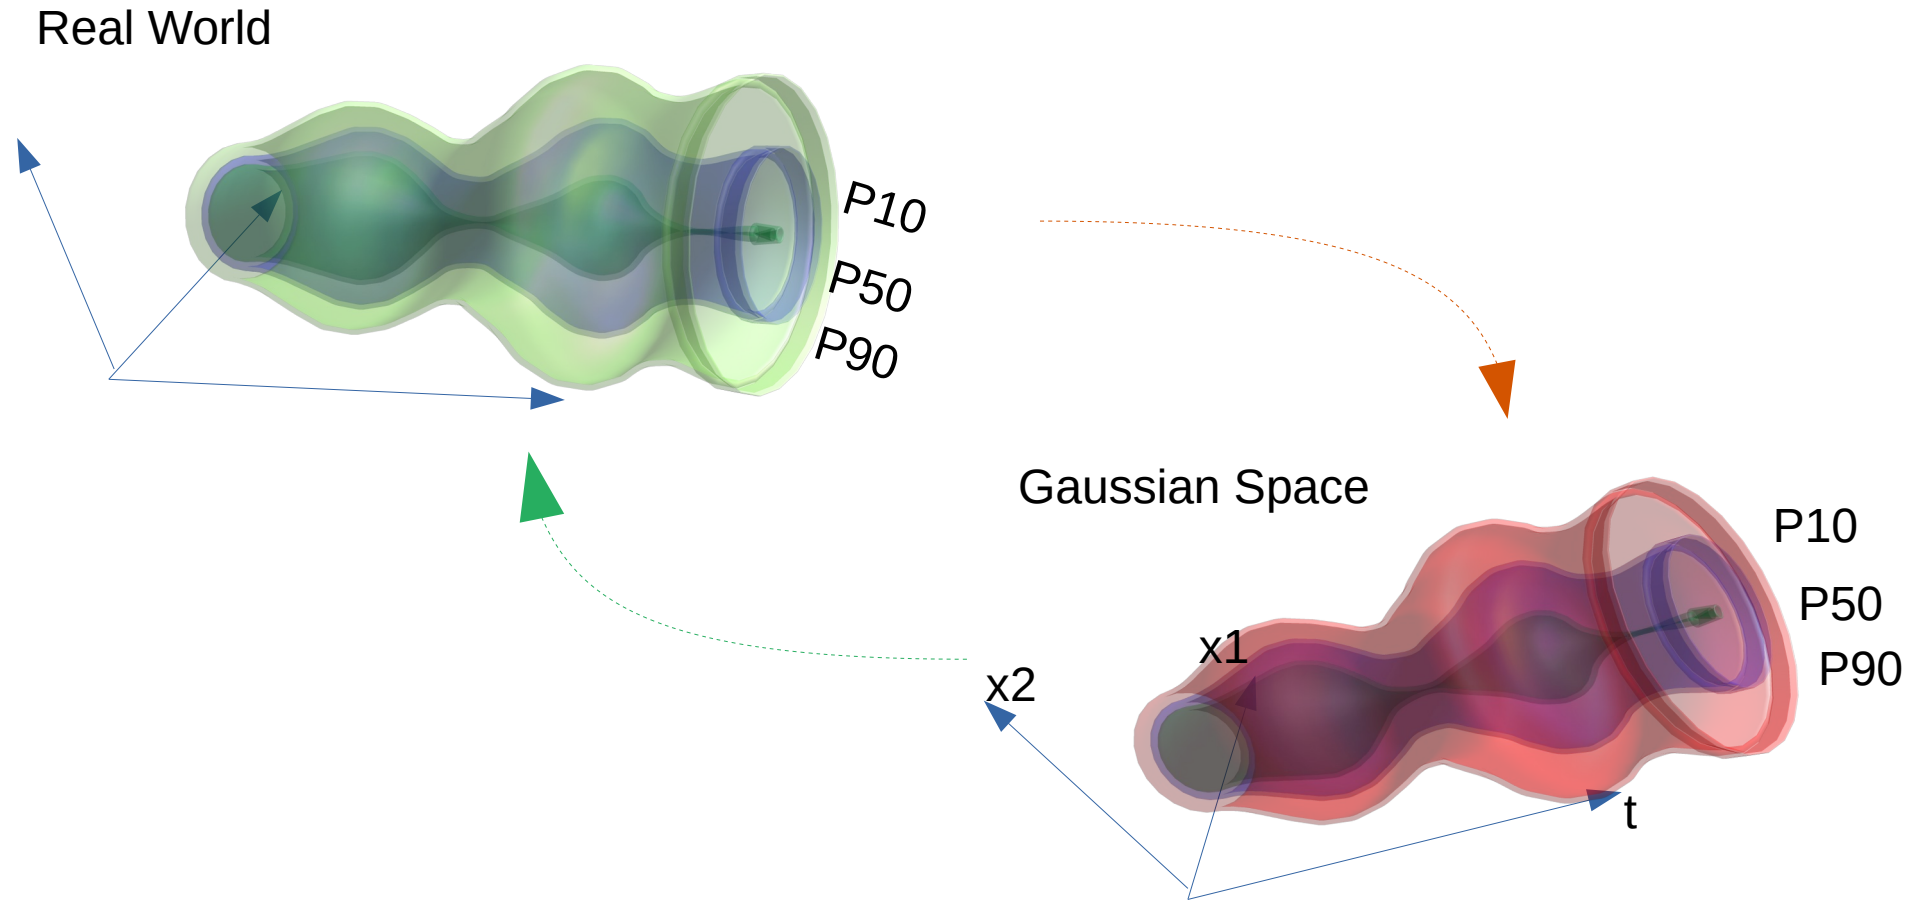

$$S_k = \begin{bmatrix} s_{1,k} \\ \dots \\ s_{n,k} \end{bmatrix} \quad F_k = \begin{bmatrix} f_{1,k} & 0 & \dots & 0 \\ 0 & f_{2,k} & \dots & 0 \\ 0 & \dots & 0 & f_{n,k} \end{bmatrix}$$

VATES

Continuous forecast of the next
168 hours of optimal operation.

<https://vates.adme.com.uy>

<http://vates.adme.com.uy>

Espected generation by source. (Example from ADME's WEB)

Next 168 h, System Load forecast.

(Example from ADME's WEB)

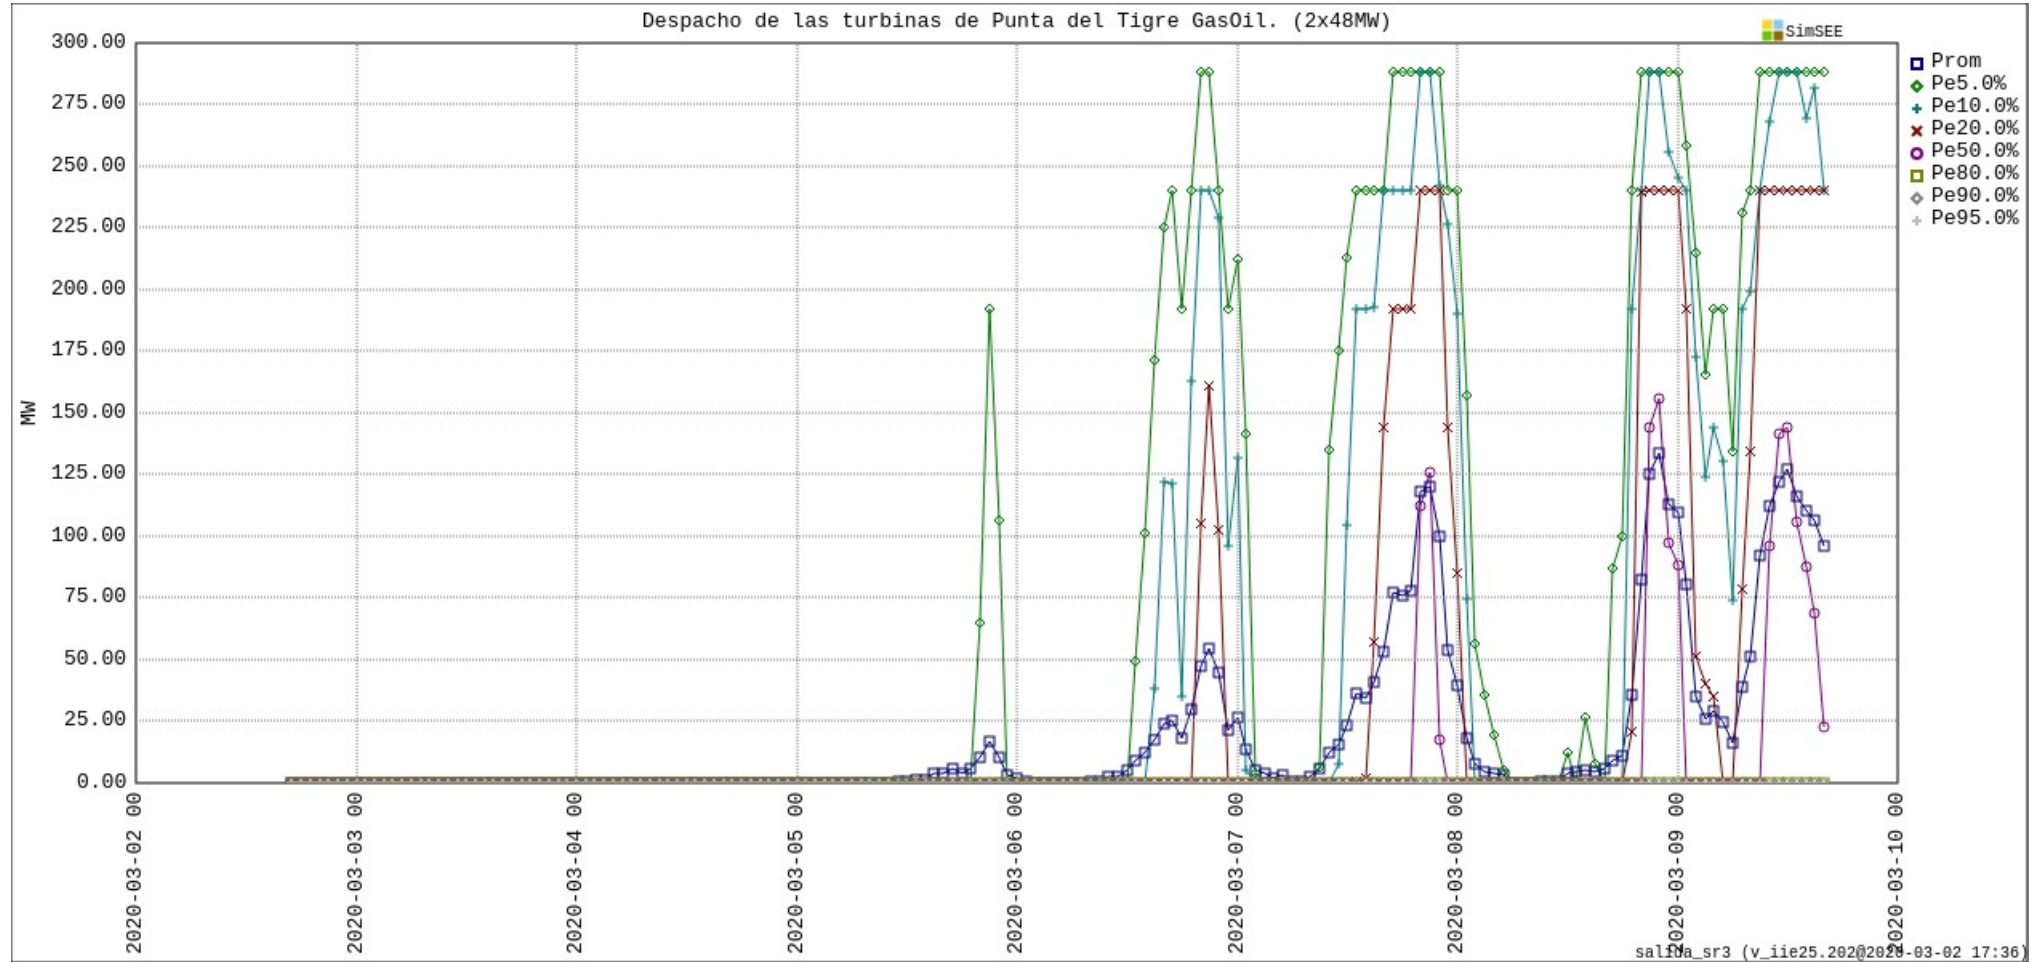

Next 168 h, Windpower forecast.

(Example from ADME's WEB)

Next 168 h, “Punta del Tigre” energy-dispatch forecast.

(Example from ADME’s WEB)

Punta del Tigre is a power plant with 6 turbine generator units burning diesel.
This information is very usefull for the system’s operators.

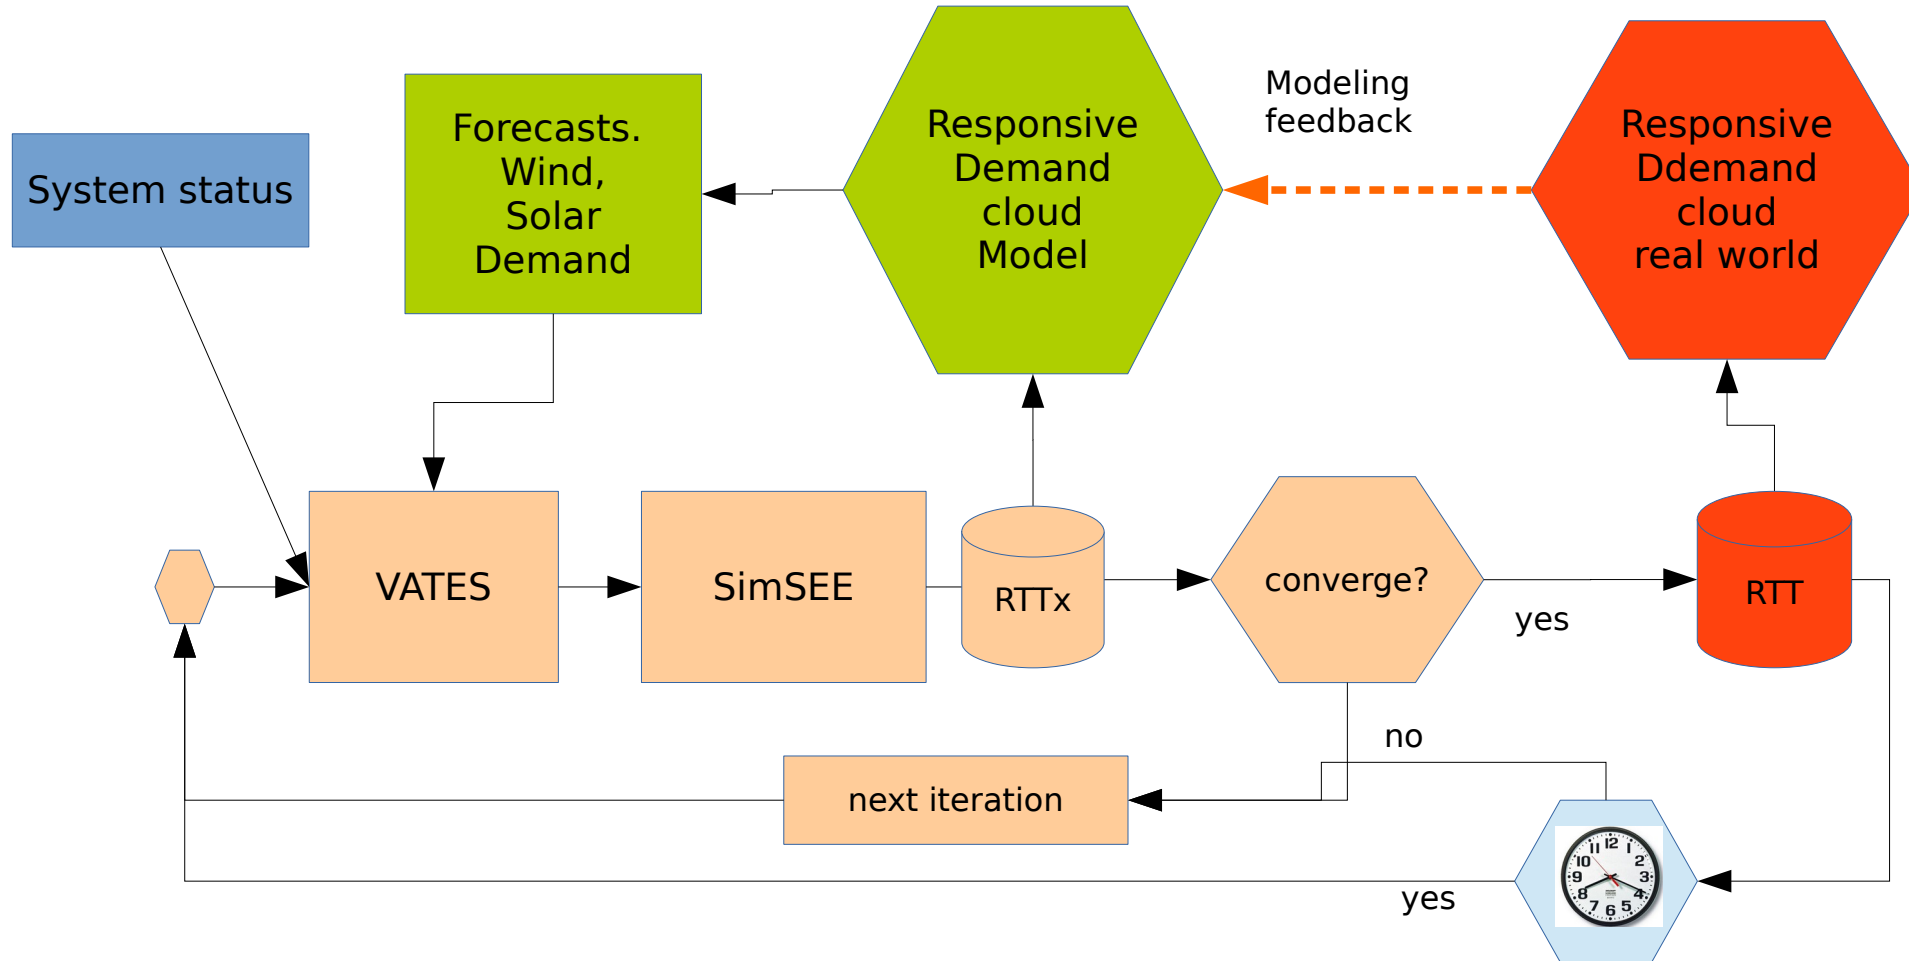

Next 168 h, Spot Price forecast.

(Example from ADME's WEB)

This information is published to allow Responsive Demand projects to grow.

In the future, VATES will close the loop with a self-learning model of Responsive Demand to avoid spot price oscillations.

**That's all folks.
Thank you so much for your attention!**

... and let's continue exploring the future!
